The reduction in size is necessary to improve the portability of these devices. This has resulted in a greater demand for smaller power supplies, which requires smaller power transformers. As the power transformers become smaller, the overall size of the transformers becomes very important. Generally, the smaller the transformer, the larger the number of turns, for a given magnetic material. The number of turns is determined by the physical size of the transformer core and the relationship between the flux density and the width of the core, which is a function of the number of turns. Power transformers can be made from any number of non-magnetic materials, such as plastics, metals, or glass. Conventional power transformers can be classified as being "soft" or "hard" types. Soft power transformers are usually made of epoxy based material which is molded into the desired shape. These soft power transformers have good electrical properties and are inexpensive. However, soft power transformers are not capable of achieving a high magnetic permeability. The 2d92ce491b
